Dell Technologies announces a hyperconverged infrastructure platform with autonomous configuration and management capabilities-- the PowerOne, a means to deploy and maintain the on-premises portion of hybrid clouds.

PowerOne systems feature pre-integrated compute, storage, networking and data protection system from the Dell EMC PowerEdge, PowerMax, PowerSwitch and PowerProtect lines. The result, the company says, is the simplest way for customers to consume Dell EMC infrastructure, down to the fact the platform also supports virtualisation software from the Dell VMware unit.

Customers can use Kubernetes and Ansible workbooks to have the PowerOne autonomously perform thousands of tasks in areas such as deployment, provisioning and ongoing operations. As Dell EMC puts it, users need to choose an outcome before the PowerOne orchestrates the automated tasks required for the outcome, such as a workload-ready VMware cluster. Business and solution providers can also leverage a system-level API to link PowerOne resources to service portals and other existing tools, creating programming "infrastructure as code" environments.
